

## Supplemental figure legends

### Figure S1

Volcano plot showing that the background binding profiles of control beads and anti-GFP beads are very similar in worms that do not express GFP fusion proteins. Proteins cross-reactive to the anti-GFP beads (highlighted in red) were filtered out from the results of pull-down assays with GFP fusion proteins.

### Figure S2

**Pull-down simulation benchmark experiment.** To simulate the detection of label-free pull-down enrichment in a complex non-specific background, two predefined samples were measured in succession in triplicate. Sample 1: 1X *E. coli* lysate, 1X UPS2 human standard, recombinant CDC42; Sample 2: 1X *E. coli* lysate, 4X UPS2 human standard, recombinant RAC1, RHOA and GFP. A combined threshold (hyperbolic curves) was set based on a modified  $t$ -statistic ( $s_0 = 1.5$ ,  $t_0 = 0.8$ ).

### Figure S3

**Validation of CAR-1 interaction partners by co-immunoprecipitation and Western blotting.** Three examples demonstrating specific binding of GFP::CAR-1 to CAR-1, IFET-1, and SPN-4 proteins in experimental but not control pulldowns. Gamma-Tubulin was a non-specific background binder in the N2 pull-downs.

### Figure S4

**High-resolution embryo IVI map with protein names.**

### Figure S5

**Depletion of *gei-12* by RNAi disrupts P granule formation in N2 early embryos.** Knocking down the paralogs of *gei-12* individually by RNAi in N2 embryos did not impair P granule assembly. Fixed embryos were stained with K76 antibody against P granules.

### Figure S6

**Depletion of *gei-12* by RNAi does not affect asymmetric localization of some other known P granule components (CAR-1, PIE-1, POS-1 and SPN-4) during early embryogenesis.**

### Figure S7

***GEI-12* and its paralogs play partially redundant roles in P granule assembly.** Strains harboring mutations in *gei-12* (*tm4259* or *tm4526*) and its paralog *C36C9.1* (*tm4343*) were fixed and stained with K76 antibody against P granules, without or with RNAi against each member of the *gei-12* family. The P granule phenotype elicited by *gei-12(RNAi)* was considerably weaker in the two *gei-12* mutant backgrounds than in wild type (Fig. S5). RNAi against either *gei-12* paralog affected the P granule phenotype of *gei-12* mutants to variable extents, but had no obvious effect in the *tm4343* mutant background or in wild type (Fig. S5). The apparent lower penetrance of the *gei-12(RNAi)* phenotype in the *gei-12(tm4259)* and *gei-12(tm4526)* mutants may be due to different genetic backgrounds and/or the generally high variability of RNAi experiments and P granule phenotypes that were also observed by Wang et al., 2014.
